

ABSTRACT OF THE DISCLOSURE

A carton for dispensing articles such as cups while retaining the remaining cups in the open carton. A plurality of panels are connected together to define a carton. A bottom
5 panel includes a plurality of article-receiving openings therethrough. The openings are configured to receive articles and to retain the articles by their top flanges. Each of the openings is disposed adjacent to a fold line connecting the bottom panel with a side panel. The fold line includes a frangible portion that is positioned in proximity of at least one of the openings. Moving each article within the respective opening permits a flange of that
10 article to initiate breakage of the frangible portion to release that article from the respective opening so that that article may be dispensed from the carton.
